

Predicting Daily Television Viewing of Senior Citizens Using Education, Age and Marital Status

Paul R. Yarnold, Ph.D.

Optimal Data Analysis, LLC

Daily television viewing (hours, 6-minute increments), marital status (0=not married; 1=married), age and education (years, integers) data were obtained for a randomly-selected sample of 25 senior citizens¹ (Table 1). Training analysis predicting viewing (dependent variable) as a linear function of the other (independent) measures by multiple regression analysis identified a statistically significant omnibus effect: $F(3,21)=11.7$, $p<0.0001$, $R^2=0.626$. Partial F (variable entered last) statistics indicated that marital status [$F(1,21)=13.9$, $p<0.0008$] and education [$F(1,21)=9.2$, $p<0.0062$] had statistically reliable negative relationships with viewing hours. This model accounted for 5/8 of the variance in television viewing time, however it was unable to make statistically reliable point predictions² of viewing times: $ESS=7.1$, $D=194.9$, *ns*. The globally-optimal (GO) novometric model predicting viewing times was: if education ≤ 13 years, then predict viewing ≤ 0.7 hours; otherwise predict viewing > 0.7 hours. Training performance (stable in jackknife analysis) was very strong: $ESS=90.1$, $D=0.20$, $p<0.0001$. The model correctly classified 3 of 3 observations having 0.7 or fewer viewing hours, and 20 of 22 (90.1%) with 0.8 or more daily viewing hours.
